

**HTML & CSS,
POSITIONING,
ASSETS, STRUCTURE**

The first thing we should talk about is structure. What is structure?

Think about a newspaper, or essays, or books, how are they structured?

They have headlines, articles, paragraphs, tables of content, etc.

Essentially, structure is just organization. How are we going to lay everything out? Where will all the pieces fit? That sort of thing.

There are some established conventions on best ways to organize our projects, but also, rules are meant to be broken and you can pretty much do whatever you want.

HTML stands for **HyperText Markup Language**, and it's technically not a programming language--it's a scripting language.

HTML describes the structure of pages.

```
<h1>Main Heading</h1>  
<p>Paragraph</p>  
<h2>Sub-heading</h2>  
<p>Another paragraph</p>
```

You can sort of tell that tags are basically containers. There's an opening and corresponding closing tag for each HTML tag. If you don't close your tag, you're going to run into problems.

The tag itself acts as an indication of what the content between the tags should be.

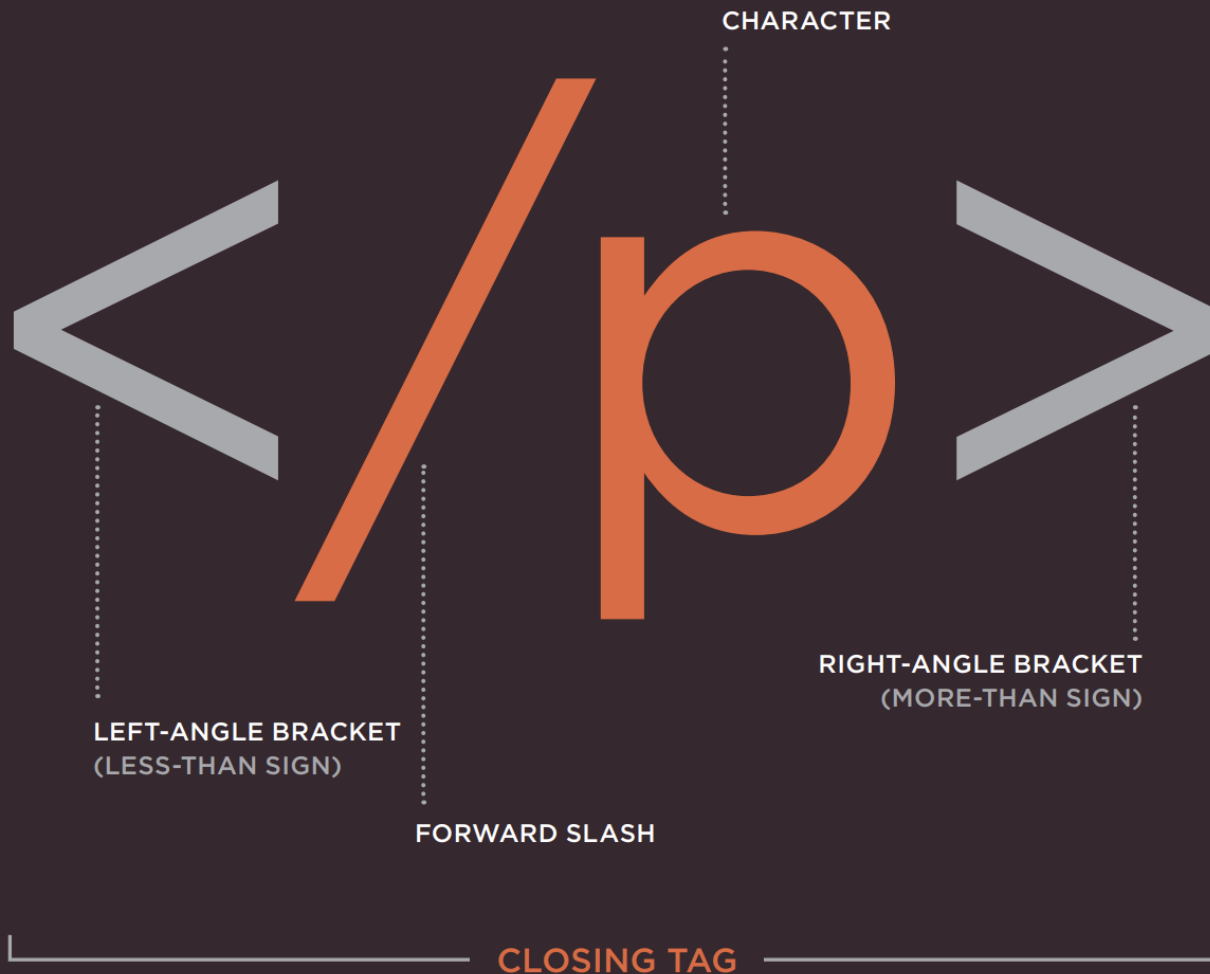

```
<section>
  <article class="post">
    <p>A bunch of content</p>
  </article>
</section>
```

The characters in the brackets indicate the tag's purpose.

For example, in the tags above the p stands for paragraph.

The closing tag has a forward slash after the the < symbol.

The terms "tag" and "element" are often used interchangeably.

Strictly speaking, however, an element comprises the opening

tag *and* the closing tag *and* any content that lies between them.

(images taken from Jon Duckett's HTML & CSS book)

```
<h2>There are several header tags, h1...h6</h2>
<section>
  <p>We can section off parts of our document.</p>
  <p>
    We can also <b>bold</b>
    text and <i>italicize</i>
  </p>
</section>
```

We can also make lists

```
<p>There are ordered lists</p>
<ol>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
</ol>
```

```
<p>And unordered lists</p>
```

```
<ul>
```

```
  <li>One</li>
```

```
  <li>Two</li>
```

```
  <li>Three</li>
```

```
</ul>
```

One of the most useful tags though, is the anchor tag, which is how we link our pages.

```
<a href="https://google.com/">Google</a>
```

Questions before we move on to folder/directory structure?

How we structure and organize our projects is up to us,
but we definitely want to emphasize organization.

Whatever you do, stay consistent, and make patterns
to help yourself later.

It might not seem terribly important when you have
one HTML page, but when you have hundreds of pages
and thousands of lines of code... it's very important.

A sample file structure:

PARENT

The *examplearts* folder is a parent of the *music* folder.

CHILD

The *music* folder is a child of the *examplearts* folder.

GRANDPARENT

The *examplearts* folder is a grandparent of the *dvd* folder.

GRANDCHILD

The *dvd* folder is a grandchild of the *examplearts* folder.

Every page and image on a website has a URL (Uniform Resource Locator). A URL is comprised of a domain name followed by the path to the resources you're looking for.

For example:

https://example.com/cool_directory/my_cool_webpage

Example.com is the domain, cool_directory is the directory (folder), and my_cool_webpage.html is the HTML file.

We also often use **relative URLs** to link our pages. This is for linking resources within our own directory structure.

This is often confusing, especially when you see things like `"../"` or `"../../"` to jump up directories.

This is a remnant of old unix systems, before GUIs were so common.

RELATIVE LINK TYPE

EXAMPLE (from diagram on previous page)

SAME FOLDER

To link to a file in the same folder, just use the file name. (Nothing else is needed.)

To link to music reviews from the music homepage:

```
<a href="reviews.html">Reviews</a>
```

CHILD FOLDER

For a child folder, use the name of the child folder, followed by a forward slash, then the file name.

To link to music listings from the homepage:

```
<a href="music/listings.html">Listings</a>
```

GRANDCHILD FOLDER

Use the name of the child folder, followed by a forward slash, then the name of the grandchild folder, followed by another forward slash, then the file name.

To link to DVD reviews from the homepage:

```
<a href="movies/dvd/reviews.html">Reviews</a>
```

PARENT FOLDER

Use ../ to indicate the folder above the current one, then follow it with the file name.

To link to the homepage from the music reviews:

```
<a href="../index.html">Home</a>
```

GRANDPARENT FOLDER

Repeat the ../ to indicate that you want to go up two folders (rather than one), then follow it with the file name.

To link to the homepage from the DVD reviews:

```
<a href="../../index.html">Home</a>
```

You may have also already noted how to add an image:

```

```

There's also several ways to **target** or **select** the HTML tag that we want to style.

The two most common are through **classes** and **IDs**.

Both a **class** and an **ID** are arbitrary in the sense that we can name them whatever we want, but we want to be precise in our naming conventions.

It doesn't make much sense to have a **section** with an **ID** of "about" if it really contains contact information.

The primary difference between a **class** and an **ID** is
the intention:

**IDS ARE UNIQUE, AND CALLED
USING A # (POUND/HASHTAG)**

**CLASSES ARE MULTIPLE, AND
CALLED USING A . (PERIOD)**

If you label something with an **ID**, it should be the
ONLY One in the entire site.

A **class** can be applied to any number of HTML tags,
but STAY CONSISTENT.

Sample HTML:

```
<nav id="primary-navigation">
  <ul>
    <li class="navigation-link">
      <a href="one.html">One</a>
    </li>
    <li class="navigation-link">
      <a href="two.html">Two</a>
    </li>
  </ul>
</nav>
```

Sample CSS:

```
nav#primary-navigation {  
    width: 100%;  
    font-size: 2em;  
}  
  
li.navigation-link {  
    color: red;  
    margin: 10px;  
}
```

This is essentially the same, just less precise:

```
#primary-navigation {  
    width: 100%;  
    font-size: 2em;  
}  
  
.navigation-link {  
    color: red;  
    margin: 10px;  
}
```

SELECTOR	MEANING	EXAMPLE
UNIVERSAL SELECTOR	Applies to all elements in the document	<code>* {}</code> Targets all elements on the page
TYPE SELECTOR	Matches element names	<code>h1, h2, h3 {}</code> Targets the <code><h1></code> , <code><h2></code> and <code><h3></code> elements
CLASS SELECTOR	Matches an element whose <code>class</code> attribute has a value that matches the one specified after the period (or full stop) symbol	<code>.note {}</code> Targets any element whose <code>class</code> attribute has a value of <code>note</code> <code>p.note {}</code> Targets only <code><p></code> elements whose <code>class</code> attribute has a value of <code>note</code>
ID SELECTOR	Matches an element whose <code>id</code> attribute has a value that matches the one specified after the pound or hash symbol	<code>#introduction {}</code> Targets the element whose <code>id</code> attribute has a value of <code>introduction</code>

CHILD SELECTOR

Matches an element that is a direct child of another

`li>a {}`

Targets any <a> elements that are children of an element (but not other <a> elements in the page)

DESCENDANT SELECTOR

Matches an element that is a descendent of another specified element (not just a direct child of that element)

`p a {}`

Targets any <a> elements that sit inside a <p> element, even if there are other elements nested between them

ADJACENT SIBLING SELECTOR

Matches an element that is the next sibling of another

`h1+p {}`

Targets the first <p> element after any <h1> element (but not other <p> elements)

GENERAL SIBLING SELECTOR

Matches an element that is a sibling of another, although it does not have to be the directly preceding element

`h1~p {}`

If you had two <p> elements that are siblings of an <h1> element, this rule would apply to both

Questions so far?

We can only go far just explaining things, so let's do a few demos to try and put these in practice.
